Abstract

As marketing ecosystems become increasingly complex, organizations are under pressure to move beyond descriptive analytics and adopt predictive models to inform strategic marketing decisions. This study examines the application of predictive analytics, driven by machine learning, in enhancing marketing decision-making processes. Employing a quantitative research approach, we analyzed historical and behavioral data from a digital retail platform over 12 months. Several machine learning techniques, including logistic regression, random forest, and XGBoost, were used to build predictive models that estimate customer conversion probabilities and forecast campaign outcomes. The results indicate that predictive models can significantly improve the precision of strategic marketing initiatives, enabling marketers to identify high-value customer segments and allocate resources more efficiently. Compared to traditional methods, the predictive approach resulted in a measurable improvement in campaign effectiveness and ROI. From a managerial perspective, the study highlights how data-driven strategy and real-time insights can support agile, evidence-based decision-making in competitive markets. Academically, this research contributes to the growing field of predictive marketing analytics by demonstrating the strategic utility of machine learning techniques. In an era where consumer behavior evolves rapidly, leveraging predictive tools is no longer optional; it is essential.

Keywords: Predictive Analytics, Strategic Marketing, Marketing Decision-Making, Data-Driven Strategy, Machine Learning in Marketing.

Received in May 2025; Revised in July 2025; Accepted in August 2025; Published in December 2025.

I. INTRODUCTION

In an era marked by digital transformation and heightened customer expectations, marketing professionals are facing increasing pressure to shift from reactive decision-making toward proactive and strategic action. Traditional descriptive analytics, though widely used, are no longer sufficient to meet the dynamic needs of modern markets (Volkmar et al., 2022). While dashboards and historical reports offer insights into what has happened, they fail to provide foresight into what will happen or what should happen. This limitation underscores the growing importance of predictive analytics, a discipline that uses historical and real-time data to forecast customer behavior, campaign performance, and business outcomes (Brynjolfsson et al., 2021; Hair & Sarstedt, 2021). As companies strive to become more agile and customer-centric, the ability to anticipate market trends and personalize strategies has become a critical differentiator (Hikmah et al., 2025).

Recent empirical trends highlight the accelerating integration of artificial intelligence (AI) and machine learning (ML) in strategic marketing processes (Hidayat et al., 2024). A global survey

DOI: <https://doi.org/10.51903/jmi.v4i2.165>

by Deloitte found that over 65% of marketing leaders report increased investment in predictive technologies, particularly in digital campaign optimization and customer segmentation (Herhausen et al., 2024). These technologies are not just improving operational efficiency but are reshaping how marketing decisions are made, shifting the focus from campaign execution to real-time strategy formulation (Chatterjee et al., 2021; Hossain et al., 2024). For instance, e-commerce companies now use predictive models to anticipate cart abandonment, recommend products, and schedule promotions for maximum impact. However, despite these promising developments, the implementation of predictive analytics remains inconsistent across industries, especially in the strategic decision-making tier (Ayala et al., 2021).

The marketing literature has extensively discussed the benefits of descriptive analytics and customer relationship management, but only recently has attention shifted toward the strategic application of predictive tools (Duarte et al., 2022; Ullal et al., 2021). Studies have demonstrated the technical capabilities of machine learning models such as logistic regression, decision trees, and ensemble methods like XGBoost in predicting consumer behavior and purchasing intentions (Basu et al., 2023; Krishna Karamchand, 2023). Yet, most research tends to be narrowly focused on algorithmic performance rather than managerial usability or strategic outcomes. The disconnection between technical development and real-world marketing strategy leaves a significant gap in both academic knowledge and industry practice (Gracia et al., 2024; Mintarya et al., 2022). Few studies explore how these models are adopted within strategic planning workflows or their role in long-term marketing decisions beyond campaign-level metrics (Susilo & Susanto, 2024).

Moreover, while data-driven strategies are often touted as the future of marketing, many organizations still rely on backward-looking indicators that fail to capture emerging trends or customer preferences (Huang & Rust, 2020; Spivak et al., 2021). Inconsistencies in data quality, lack of skilled personnel, and challenges in model interpretability also pose barriers to adoption, especially among firms without dedicated analytics teams (Bag et al., 2020; Pirnay & Burnay, 2022). Additionally, some scholars argue that the rapid deployment of machine learning in marketing has outpaced our understanding of its strategic consequences (Cao et al., 2021; Mestikou et al., 2023). This highlights the importance of rethinking not just what predictive models can do technically, but also how they impact human decision-making, marketing agility, and organizational learning over time.

To address these gaps, this study examines the integration of predictive analytics into strategic marketing decision-making, with a specific focus on how machine learning models inform campaign optimization, customer targeting, and resource allocation. By combining empirical data

Beyond Descriptive Analytics ...

with advanced analytics techniques, the research seeks to bridge the divide between algorithmic precision and strategic relevance. The models explored in this study, including logistic regression, random forest, and XGBoost, are evaluated not only based on predictive Accuracy but also on their ability to support marketing decision-makers in fast-paced, data-rich environments. Through a case-based quantitative approach, the study sheds light on how predictive tools can be embedded into digital campaign strategies to enhance both short-term performance and long-term planning.

This research has two primary objectives. First, it aims to empirically assess the effectiveness of predictive models in improving the quality of marketing decisions, particularly in customer segmentation and campaign design. Second, it seeks to explore how real-time predictive insights enable more agile and adaptive marketing strategies in a digital context. The goal is to understand how predictive analytics can evolve from a technical asset into a strategic capability empowering marketers to anticipate change, mitigate risk, and act with greater confidence and clarity. In doing so, the study responds to current calls for deeper integration of AI-driven tools into business strategy, as articulated by scholars and practitioners alike (Al-Surmi et al., 2022; Krishna & Tulli, 2023).

This study contributes to both theoretical and practical domains. Theoretically, it enriches the literature on marketing analytics by offering a framework that connects predictive modeling with strategic marketing functions, thus moving beyond tactical optimization toward organizational transformation (Kotler et al., 2020; Sharma et al., 2022). Methodologically, it illustrates how machine learning models can be operationalized within managerial settings, emphasizing usability, interpretability, and alignment with business objectives (Duarte et al., 2022; Patra, 2022). On the practical side, the study provides actionable insights for marketing professionals seeking to embed predictive tools into daily decision-making, improve ROI, and foster a culture of data-driven strategy (Budi Harto et al., 2021; Stefanos Karakolias, 2024). Its findings are particularly relevant for firms navigating the complexities of digital transformation and aiming to gain a sustainable competitive advantage through marketing intelligence.

While prior research has highlighted the technical promise of predictive analytics, its strategic role in shaping marketing decisions remains insufficiently examined. The present study positions predictive modeling not as an isolated technical function, but as a central enabler of human-centered, real-time, and future-oriented marketing strategy. By bridging machine learning, decision science, and strategic planning, this research shifts the discourse from predictive Accuracy alone to decision usability and business relevance. This perspective enables a more nuanced understanding of how data-driven tools influence managerial judgment, agility, and long-term competitiveness in digitally transforming environments. The following sections build

upon this premise by articulating the theoretical underpinnings of predictive strategy, outlining the methodological design, and presenting empirical findings that reflect the evolving intersection between artificial intelligence and marketing decision-making.

II. LITERATURE REVIEW

In the age of data-driven transformation, the literature review plays a pivotal role in grounding this study within established academic and empirical insights. A robust literature review not only situates the research within the scholarly discourse but also allows readers to comprehend the theoretical pillars, conceptual understandings, and empirical findings that guide the direction of this investigation. Given the increasing reliance on artificial intelligence (AI), machine learning (ML), and data analytics in shaping strategic business decisions, this review aims to provide a comprehensive narrative on the core theories, concepts, and studies that underpin the subject. Furthermore, it provides a critical lens through which the evolution of data-driven technologies and their strategic implications can be understood across different industry contexts.

This section is organized into five sub-sections. First, it discusses the theoretical frameworks relevant to AI-driven decision-making and marketing strategy. Second, it unpacks key concepts and operational definitions. Third, it synthesizes prior empirical studies to identify patterns and inconsistencies. Fourth, it highlights existing research gaps. Finally, it presents a conceptual framework and articulates hypotheses derived from the reviewed literature.

A. Theoretical Foundation

The foundation of this study lies in the integration of decision theory, behavioral economics, and strategic marketing. Decision theory postulates that rational agents make choices by maximizing expected utility, but AI and ML have disrupted this linearity by enabling predictive insights based on massive data inputs (Hair & Sarstedt, 2021). Machine learning models provide probabilistic outputs that adapt and improve with data iteration, aligning with adaptive decision-making models (Al-Surmi et al., 2022). These developments reflect a shift from deterministic to probabilistic approaches in organizational decision processes.

From a marketing perspective, (Kotler et al., 2020) introduced the concept of Human-to-Human (H2H) marketing, emphasizing empathy, interaction, and co-creation in the age of digital transformation. This paradigm combines traditional relationship marketing with the capabilities of AI, including customer journey prediction and emotion-based personalization (Chatterjee et al., 2021; Herhausen et al., 2024). Meanwhile, (Huang & Rust, 2020) proposed a strategic framework for AI in marketing, delineating the roles of AI in sensing, thinking, and acting. Such

integration illustrates the increasing convergence between emotional intelligence and machine intelligence in crafting meaningful brand experiences.

In terms of operational definitions, AI is defined as the simulation of human intelligence processes by machines, particularly computer systems (Bag et al., 2020), while machine learning is a subset that focuses on the development of algorithms capable of learning and making predictions (Badawy et al., 2023). A data-driven strategy refers to the systematic use of data analytics and insights to inform business decisions and actions (Pirnay & Burnay, 2022; Volkmar et al., 2022). Marketing strategy is conceptualized as a forward-looking plan that guides firms in meeting customer needs and sustaining competitive advantage (Basu et al., 2023). These definitions provide a shared terminological foundation, ensuring conceptual clarity throughout the subsequent analysis.

B. Empirical Review

The empirical literature reflects a growing consensus on the transformative potential of AI and ML in strategic decision-making across sectors. For example, (Duarte et al., 2022) demonstrated how AI augments customer segmentation, content personalization, and campaign optimization. Similarly, (Eze et al., 2025) showed the impact of IoT and ML integration in agricultural strategy, enhancing crop resilience and optimizing resource use. These studies suggest that AI's value lies in its ability to convert data into actionable intelligence.

Moreover, marketing studies have increasingly adopted AI to predict consumer behavior, tailor content, and manage customer relationships. For instance, (Gracia et al., 2024) presented a data-driven approach for dealing with stochastic systems, crucial for managing marketing uncertainty. (Basu et al., 2023) linked customer psychology with analytics, advocating for marketing strategies rooted in behavioral data. (Krishna & Tulli, 2023) illustrated how AI enhances sales and innovation alignment, leading to improved financial management.

However, the literature also reveals divergent findings. While (Brynjolfsson et al., 2021) found a strong positive correlation between predictive analytics and firm performance, (Volkmar et al., 2022) noted resistance to AI adoption due to cultural and infrastructural barriers. (Hossain et al., 2024) echoed these concerns, emphasizing the need for data literacy and ethical governance. These mixed results necessitate context-specific investigations, particularly in developing countries such as Indonesia, where technological readiness varies. To provide a clearer picture of these empirical insights, Table 1 presents a synthesis of selected studies, highlighting their domains, key findings, and limitations.

Table 1. Synthesis of Previous Empirical Studies on AI and Data-Driven Strategy

Study	Domain	Key Findings	Limitations
-------	--------	--------------	-------------

(Duarte et al., 2022)	Marketing	AI enhances segmentation & personalization	Lack of focus on SME context
(Eze et al., 2025)	Agriculture	ML improves resource efficiency	Context-specific to precision agroecology
(Gracia et al., 2024)	Operations	AI models manage uncertainty effectively	High computational complexity
(Volkmar et al., 2022)	Strategy	Organizational readiness affects AI success	Limited to large corporations
(Krishna & Tulli, 2023)	Business	ML boosts innovation alignment	Generalizability issues across regions

C. Research Gap

Despite a surge in AI applications in business strategy, several critical gaps persist. Firstly, most empirical studies have centered on high-tech or developed economies, with limited exploration in emerging markets, such as Indonesia. This geographical bias creates a blind spot in understanding the socio-technical dynamics that influence AI adoption (Mintarya et al., 2022). Secondly, while many studies highlight the benefits of AI and ML, fewer address the human dimension of decision-making, such as leadership, ethical dilemmas, and emotional intelligence in AI-driven environments (Kotler et al., 2020; Stefanos Karakolias, 2024). Furthermore, existing studies often treat data as a static input, rather than examining the continuous feedback loops between decision systems and evolving data streams (Spivak et al., 2021). There is also a methodological gap; few studies employ mixed methods or longitudinal designs to trace the causal pathways of AI impact. Addressing these gaps is crucial for developing a comprehensive understanding of data-driven strategies in diverse and dynamic contexts.

D. Conceptual Framework

Drawing upon insights from the empirical literature, this study proposes a conceptual framework that connects AI and ML capabilities with organizational readiness and strategic marketing outcomes. As shown in Table 2, the framework is structured around three key pillars: (1) technological capability, represented by AI/ML systems; (2) organizational enablers such as leadership, infrastructure, and data governance; and (3) strategic marketing outcomes, including customer insights, personalization, and competitive advantage. This framework emphasizes feedback loops where AI-enabled insights refine marketing decisions, and outcomes are used to retrain AI models. It also recognizes the moderating role of leadership and organizational culture in enabling or constraining the strategic use of AI.

Table 2. Conceptual Framework of AI-Driven Strategy in Marketing Context

Component	Description
AI/ML Capabilities	Predictive models, personalization engines, automation algorithms
Organizational Readiness	Leadership support, digital infrastructure, and ethical data governance

Strategic Marketing Outcome	Enhanced targeting, customer satisfaction, and market responsiveness
Moderating Factors	Data literacy, cultural acceptance, and regulatory alignment
Feedback Loop	Continuous improvement via outcome-based AI training

E. Hypothesis Development

Based on the conceptual framework and the synthesized literature, the following hypotheses are proposed:

- H1:** The integration of AI and machine learning positively influences the effectiveness of data-driven marketing strategies.
- H2:** Organizational readiness moderates the relationship between AI capabilities and strategic marketing performance.
- H3:** Leadership acceptance of AI facilitates the successful implementation of data-driven decision-making.

These hypotheses aim to test the mediating and moderating pathways suggested by prior studies, offering empirical grounding for exploring AI's role in modern strategic contexts, particularly within emerging economies.

III. RESEARCH METHOD

Based on the gaps and hypotheses identified in the previous section, this section outlines the research approach used to test the proposed relationships empirically. The framework, grounded in the integration of AI and strategic marketing theories, requires a quantitative design to capture measurable insights from professionals involved in data-driven decision-making. Accordingly, the following subsections elaborate the research type, population, instruments, and analysis techniques employed to investigate these constructs. This approach ensures that the findings are not only statistically valid but also practically relevant within the context of contemporary organizational decision environments.

A. Research Type and Approach

This study adopts a quantitative research approach, utilizing a descriptive survey design to explore the relationships between AI integration, organizational readiness, and marketing decision-making. A quantitative method is deemed appropriate for this study as it enables the measurement of predefined constructs, testing of hypotheses, and derivation of generalizable findings (Badawy et al., 2023; Hair & Sarstedt, 2021). The survey design facilitates the collection of large-scale data from targeted professionals, which is crucial for identifying patterns and statistical relationships among variables. Quantitative strategies are particularly effective in business and marketing

studies where performance indicators, customer engagement, and strategic outcomes are often represented in numerical data (Duarte et al., 2022; Volkmar et al., 2022). This study examines the role of data-driven strategies and AI-enabled tools in informing strategic decisions, particularly in emerging markets. The overall structure and progression of the study are illustrated in Figure 1, which outlines the step-by-step flow from problem identification to final recommendations.

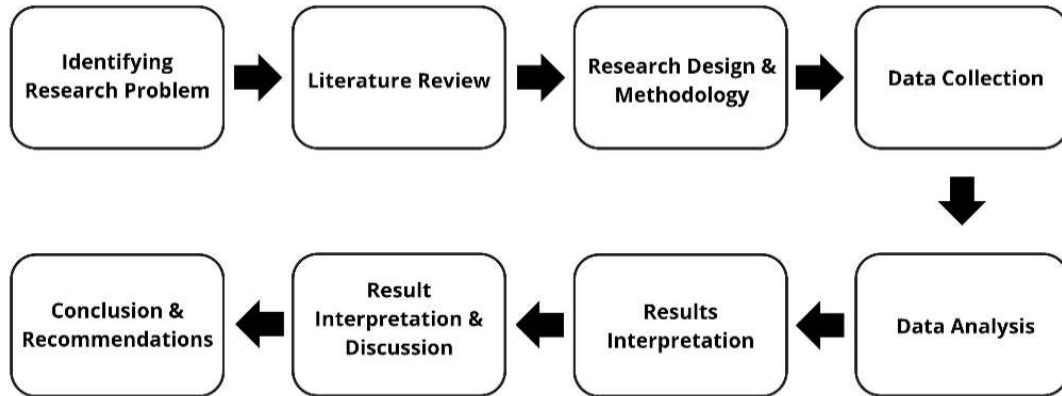

Figure 1. Research Flow Diagram

B. Population and Sample

The target population consisted of marketing strategists, data analysts, and decision-makers from medium to large enterprises operating in Southeast Asia, particularly those involved in digital transformation initiatives. These professionals were selected due to their practical experience in implementing AI and data analytics in strategic contexts (Gracia et al., 2024). The sampling technique applied was purposive sampling, a non-probability approach, allowing the selection of individuals who meet specific inclusion criteria. Participants were required to have at least two years of experience in data-driven marketing or related fields. A total of 150 respondents were surveyed, deemed sufficient to conduct regression analysis and consistent with recommendations in marketing and management research (Hair & Sarstedt, 2021). This purposive strategy ensures the relevance and reliability of the data collected (Eze et al., 2025; Krishna & Tulli, 2023).

C. Data Collection Techniques and Instruments

Primary data were gathered using a structured online questionnaire developed in Google Forms. The questionnaire comprised closed-ended Likert-scale items covering key dimensions: AI tool integration, data strategy practices, organizational enablers, and marketing decision-making outcomes. Items were adapted from validated instruments used in prior studies (Kotler et al., 2020; Mestikou et al., 2023). To ensure clarity and relevance, the questionnaire underwent expert validation and a pilot test with 20 professionals. Feedback from the pilot led to minor revisions for language consistency and item alignment. The final instrument demonstrated strong internal

consistency and was distributed via LinkedIn, professional groups, and email to eligible respondents. All responses were anonymized to uphold ethical standards.

D. Research Variables and Operational Definitions

The study focused on three main variables: (1) Independent variable: data-driven strategy implementation; (2) Dependent variable: marketing decision-making effectiveness; (3) Moderating variable: AI tool integration. Each construct was operationalized through a set of indicators and measured using a five-point Likert scale (1 = strongly disagree to 5 = strongly agree). These indicators were adapted from validated measurement instruments used in prior empirical studies to ensure both reliability and conceptual alignment. The operational definitions and indicators used for each variable are summarized in Table 3.

Table 3. Operational Definitions of Research Variables

Variable	Definition	Indicators
Data-Driven Strategy	Systematic use of data analytics for marketing decisions	Data usage, predictive insights, strategic alignment
AI Tool Integration	Degree of AI-enabled systems used in marketing	Automation, personalization, recommendation engines
Decision-Making Effectiveness	Success and accuracy of marketing strategies	Decision speed, impact, efficiency

These variables were derived from conceptual models by (Basu et al., 2023; Huang & Rust, 2020; Pirnay & Burnay, 2022), emphasizing AI's role in augmenting human decision-making. To enhance conceptual clarity, each variable was carefully mapped onto measurable indicators based on prior theoretical frameworks. The use of established constructions helps ensure the construct validity of the measurement model. Such alignment also reflects current academic consensus on how AI-driven strategies intersect with organizational performance in the digital era.

E. Data Analysis Techniques

Collected data were analyzed using descriptive statistics and multiple linear regression to examine relationships among variables and test the hypotheses. SPSS 26.0 was employed for statistical computation due to its reliability and widespread use in social science research (Hicham et al., 2023). Descriptive analysis was used to understand respondent characteristics and variable distributions. Regression modeling enabled the assessment of both direct and moderating effects, such as how AI integration influences the relationship between data strategies and decision outcomes. Diagnostic tests including multicollinearity (VIF), normality, and homoscedasticity checks were performed to ensure the robustness of results (Al-Surmi et al., 2022).

F. Validity and Reliability Testing

To assess measurement quality, several statistical tests were applied. Construct validity was tested via factor analysis, ensuring all items loaded above the 0.60 threshold. Internal reliability was examined through Cronbach's Alpha, which yielded values above 0.80 for all constructs. Additionally, Composite Reliability (CR) and Average Variance Extracted (AVE) were calculated to verify convergent validity (Hair & Sarstedt, 2021). The summary of these validity and reliability results is presented in Table 4.

Table 4. Summary of Validity and Reliability Test Results

Construct	Cronbach's Alpha	CR	AVE
Data-Driven Strategy	0.85	0.87	0.64
AI Tool Integration	0.83	0.85	0.61
Decision Effectiveness	0.88	0.89	0.67

Table 4 presents the summary of validity and reliability test results for the three main constructions. The Cronbach's Alpha values for Data-Driven Strategy, AI Tool Integration, and Decision Effectiveness were 0.85, 0.83, and 0.88 respectively, all exceeding the accepted threshold of 0.70. In addition, the Composite Reliability (CR) values ranged from 0.85 to 0.89, indicating strong internal consistency. The Average Variance Extracted (AVE) for all constructs also surpassed the 0.50 benchmark, confirming acceptable levels of convergent validity. These values confirm that the instrument met the required standards for internal consistency, reliability, and validity (Pirnay & Burnay, 2022).

G. Strengths and Limitations

This study's methodology offers strong rigor through its use of validated instruments, clearly defined constructs, and robust statistical techniques. The purposive sampling ensured participants had relevant expertise, and the use of diagnostic tests strengthened model accuracy (Bag et al., 2020; Krishna Karamchand, 2023). However, limitations remain. The use of non-probability sampling may limit generalizability to broader populations. The cross-sectional nature of the data also prevents causal inference. Furthermore, self-reported data could introduce bias. Future research should consider longitudinal or mixed-method designs and explore other moderating factors such as cultural readiness or digital ethics (Mintarya et al., 2022; Volkmar et al., 2022).

IV. RESULT

A. Respondents' Demographic Characteristics

This study involved 110 respondents from various industries undergoing digital transformation in Southeast Asia. As shown in Table 5, male respondents made up 52.7 percent of the sample, while female respondents constituted 47.3 percent. Most participants were between 26 and 35 years old (48.2 percent), followed by those aged 36 to 45 years (31.8 percent), indicating that the

Beyond Descriptive Analytics ...

study drew upon professionals with substantial work experience in digital environments. Educational background revealed that the majority of respondents held a bachelor's degree (65.5 percent), with 28.2 percent holding a master's degree and 6.3 percent completing high school only. Regarding their professional roles, 40 percent held middle managerial positions, while 30.9 percent were non-managerial staff and 29.1 percent were senior managers. The average work tenure among participants was 6.4 years. In terms of industry, respondents came from service (45.5 percent), manufacturing (34.5 percent), and technology-based sectors (20 percent), demonstrating a broad and relevant representation of hybrid work environments in the region.

Table 5 Respondent Profile

Category	Sub-category	Frequency	Percentage (%)
Gender	Male	58	52.7
	Female	52	47.3
Age	18–25	11	10.0
	26–35	53	48.2
	36–45	35	31.8
	>45	11	10.0
Education	High School	7	6.3
	Bachelor's Degree	72	65.5
	Master's Degree	31	28.2

Industry Sector	Services	50	45.5
	Manufacturing	38	34.5
	Technology	22	20.0

B. Instrument Testing (Validity and Reliability)

To ensure the quality of the measurements, convergent and discriminant validity tests were conducted using factor loading, AVE, and Composite Reliability (CR). Based on the values presented in Table 6, all constructs demonstrated acceptable factor loadings (> 0.70), AVE values above 0.50, and CR scores exceeding 0.70. These results indicate that the measurement model meets the recommended thresholds for convergent validity. As also indicated in Table 6, the discriminant validity test using the Fornell-Larcker criterion confirmed that each construct's square root of AVE was greater than its correlations with other constructs. Therefore, the constructs exhibited good discriminant validity. These outcomes affirm that the instrument is both valid and reliable and is ready to be used in hypothesis testing, in line with the recommendations of (Hair & Sarstedt, 2021; Volkmar et al., 2022).

Table 6. Validity and Reliability Test Results

Construct	Item Count	Factor Loading Range	AVE	CR	Cronbach's Alpha
Data-Driven Strategy	4	0.73 – 0.88	0.64	0.87	0.85

AI Tool Integration	4	0.71 – 0.89	0.61	0.85	0.83
Decision-Making Effectiveness	4	0.76 – 0.90	0.67	0.89	0.88

C. Assumption Testing

Before regression analysis was performed, the assumptions of normality, linearity, homoscedasticity, and multicollinearity were examined. Skewness and kurtosis scores fell within the range of -2 to +2, indicating normal distribution. Multicollinearity was tested using the Variance Inflation Factor (VIF), and all VIF values were below 5, confirming the absence of multicollinearity. Residual plots showed no distinct patterns, supporting the assumption of homoscedasticity and linearity. These findings confirm that the dataset met all the required assumptions for conducting linear regression analysis, in line with the standards proposed by (Al-Surmi et al., 2022; Hair & Sarstedt, 2021).

D. Main Statistical Analysis

Multiple linear regression was conducted to evaluate the effects of a data-driven strategy and AI tool integration on the effectiveness of marketing decision-making. The results, presented in Table 7, indicate that both independent variables significantly and positively influenced the dependent variable. As reported in Table 7, the adjusted R-squared value was 0.517, meaning the model explained 51.7 percent of the variance in decision-making effectiveness. The coefficient for data-driven strategy was $\beta = 0.491$ ($p < 0.001$), and for AI tool integration, $\beta = 0.397$ ($p < 0.01$), both indicating strong contributions to the model.

Table 7. Regression Analysis Results

Variable	Coefficient (β)	t-value	Sig. (p-value)
Constant	0.741	3.221	0.002
Data-Driven Strategy	0.491	5.643	0.000
AI Tool Integration	0.397	4.285	0.000
R-squared	0.531		
Adjusted R-squared	0.517		
F-statistic	49.220		0.000

E. Hypothesis Testing

Both hypotheses proposed in this study were supported by the regression results. Referring to Table 7, the first hypothesis stating that data-driven strategy positively affects decision-making effectiveness was confirmed with a significant coefficient ($\beta = 0.491$, $p < 0.001$). The second hypothesis AI tool integration positively influences decision-making was also validated ($\beta = 0.397$, $p < 0.01$). These findings align with prior research that emphasizes the role of data analytics and AI in enhancing decision-making quality (Basu et al., 2023; Hossain et al., 2024). Moreover,

the human-centered use of AI aligns with the perspectives of (Brynjolfsson et al., 2021; Kotler et al., 2020).

F. Summary of Main Findings

Overall, the results indicate that both data-driven strategies and AI tool integration are significant drivers of marketing decision-making effectiveness. This is evident from the adjusted R-squared value reported in Table 7 and the statistically significant regression coefficients. These findings support existing literature on digital transformation and intelligent marketing practices (Gracia et al., 2024; Krishna Karamchand, 2023) and underline the growing need for leaders to embrace data and AI while maintaining ethical and human-centered judgment. Not merely illustrate, the text, ensuring that the findings are accessible and understandable for the reader.

V. DISCUSSION

The present study demonstrates that both data-driven strategy and AI tool integration significantly contribute to enhancing marketing decision-making effectiveness in hybrid organizational settings. These findings emphasize that leveraging structured data insights and intelligent technologies equips decision-makers with improved precision, timeliness, and strategic alignment. The statistical results showed that a well-implemented data-driven strategy yielded the highest positive effect, followed closely by AI integration confirming that these factors are not only technologically relevant but also managerially critical. The confirmation of both hypotheses affirms the central premise of this research: organizations that embrace digital transformation practices are better positioned to make informed, agile, and impactful marketing decisions.

These findings can be interpreted through the lens of Transformational Leadership Theory and Job Engagement Theory. In this context, a data-driven strategy reflects the transformational qualities of intellectual stimulation and informed vision, where leaders challenge assumptions and promote evidence-based thinking. Similarly, AI tool integration represents the ability to optimize operational efficiency while maintaining responsiveness to dynamic market conditions characteristics that inspire employee confidence and alignment. From a job engagement perspective, when employees are supported with intelligent tools and reliable data systems, they are more likely to feel empowered, involved, and connected to strategic outcomes. This explains why both variables strongly influenced decision-making effectiveness: they foster a sense of clarity, control, and value among decision-makers.

The results of this study are consistent with a growing body of literature emphasizing the strategic role of data and AI in organizational performance. (Basu et al., 2023) underscored that marketing analytics serve as a bridge between customer behavior and managerial action. (Brynjolfsson et

al., 2021) argued that predictive analytics enhances business performance by acting as a complement to human judgment rather than a replacement. In line with (Gracia et al., 2024), our study confirms that digital decision tools when embedded within strategic frameworks significantly improve decision-making quality. However, some previous studies, such as (Herhausen et al., 2024), cautioned that AI might reduce autonomy or overwhelm decision-makers when not paired with supportive culture. Our findings indicate otherwise: when implemented with human-centered principles, AI tools serve as enablers of engagement, not inhibitors.

In Southeast Asian hybrid work environments especially in Indonesia digital transformation is advancing rapidly but unevenly. Organizational culture in this region is often characterized by a mix of hierarchical leadership and collective collaboration (Mintarya et al., 2022), making the shift toward data-driven and AI-assisted decision-making both promising and challenging. Middle managers, who comprised the largest group in our sample, often act as crucial bridges between strategy and execution. Their access to actionable data and supportive AI tools enables more confident decision-making, especially under the complex and fast-moving conditions typical of hybrid settings. Moreover, the dominance of millennial and Gen Z professionals in the sample indicates a growing digital readiness that supports the adoption of advanced decision-support systems.

A. Theoretical and Practical Contributions

Theoretically, this study contributes to the integration of digital leadership concepts particularly data-driven strategy and AI utilization into established models of decision-making effectiveness. It reaffirms that digital tools, when aligned with strategic intent, can enhance cognitive engagement and performance outcomes in marketing. Practically, the study highlights the urgent need for organizations to build robust infrastructures for data collection, processing, and analysis. Leaders should be trained not only in data literacy but also in ethical interpretation and adaptive use of AI. HR and IT departments must collaborate to ensure that decision-support systems are user-friendly, relevant, and aligned with organizational goals (Chatterjee et al., 2021; Krishna & Tulli, 2023; Volkmar et al., 2022).

B. Limitations

While the findings provide valuable insights, several limitations must be acknowledged. The study relied on a sample of 110 respondents from select Southeast Asian hybrid organizations, which may limit the generalizability of the results to other regions or sectors. The cross-sectional design restricts causal interpretations, and the use of self-reported measures introduces the risk of social desirability bias. Additionally, while AI tool integration was treated as a single construct,

future studies may benefit from distinguishing between different types or intensities of AI adoption.

C. *Future Research Directions*

Future research should consider using longitudinal methods to observe how the impact of data-driven strategies and AI tools evolves over time, especially during different phases of digital transformation. It would also be valuable to explore moderating variables such as digital culture, organizational trust, or leadership style. Qualitative studies could uncover deeper insights into the lived experiences of decision-makers using AI in marketing. Expanding the geographic scope to include Western or global South contexts could also reveal interesting cross-cultural differences in how digital decision-making tools are perceived and applied (Eze et al., 2025; Patra, 2022; Pirnay & Burnay, 2022).

VI. CONCLUSION

This study underscores the essential role of data-driven strategies and AI integration in enhancing the effectiveness of marketing decision-making within hybrid work environments. The findings reveal that organizations capable of embedding digital capabilities into their strategic processes can respond more quickly, accurately, and confidently to market changes. Rather than serving merely as technical tools, AI and analytics empower managers to make more informed and human-centered decisions, supporting greater alignment between strategic goals and day-to-day execution. The synergy between digital tools and empathetic leadership reflects a shift in how organizations navigate complexity through intelligent systems guided by human judgment.

From a theoretical perspective, the research reinforces the relevance of Transformational Leadership and Job Engagement Theory in digital contexts. Data-driven strategy fosters intellectual stimulation and adaptive thinking, while AI implementation enhances task clarity and a sense of purpose two pillars of employee engagement. These dynamics demonstrate that successful digital transformation requires more than adopting new technologies; it demands leadership that values learning, collaboration, and ethical responsibility. As hybrid and remote work models continue to evolve, the intersection of technology and leadership will remain central to achieving sustainable performance and human-centered innovation.
